NORTH DAKOTA STATE UNIVERSITY

Annual Research Report No. 92
December 2017

NDSU NORTH DAKOTA
STATE UNIVERSITY

NDSU Research and Extension Faculty and Staff Involved with the Langdon Research Extension Center

| | |
|-------------------------|----------------------------------------------|
| Randy Mehlhoff | Director |
| Bryan Hanson | Research Agronomist |
| Dr. Venkat Chapara | Assistant Research Professor/Plant Pathology |
| Naeem Kalwar | Area Extension Specialist/Soil Health |
| Lesley Lubenow | Area Extension Specialist/Agronomy |
| Sara Schuchard-McGregor | Administrative Assistant |
| Travis Hakanson | Research Specialist/Agronomy |
| Lawrence Henry | Research Specialist/Agronomy |
| James Chaput | Research Technician/Foundation Seed |
| Amanda Arens | Research Specialist/Plant Pathology |
| Carmen Ewert | Research Technician/Foundation Seed |
| Allison Thompson | Farm Business Management Instructor, LRSC |
| Dr. Anitha Chirumamilla | Cavalier County Extension Agent |
| Macine Lukach | Cavalier County Extension Agent |

2017 Seasonal Employees

| | | | |

The 2017 annual research report is intended to provide producers information to aid in selecting varieties and/or hybrids. Variety information and research reports on crop disease and production can also be found on our website www.ag.ndsu.edu/langdonrec/. Variety trial results from all NDSU Research Extension Centers and the Main Station at Fargo, along with crop extension bulletins, can be accessed on the web at www.ag.ndsu.edu/varietytrials/.

Choosing a variety is one of the most important decisions a producer makes in successful crop production. Characteristics to consider in selecting a variety may include yield potential, disease resistance, protein content, straw strength, plant height, test weight, yield stability across years and locations, quality and economic profitability. A variety's performance may differ from year to year and from location to location within a year due to varying environmental conditions. When selecting a variety to grow, it is best to consider a variety's performance over several years and locations.

The agronomic data presented in this publication are from replicated research plots using experimental designs that enable the use of statistical analysis. The trials are designed so that "real" yield and agronomic differences can be statistically separated from differences that occur by chance. The least significant difference (LSD) values given in the report are used for this purpose. For example, if the LSD 10% is five bushels, then if the difference between any two varieties is greater than five bushels they are said to be significantly different from one another 90 times out of 100 under those growing conditions. If the difference between two varieties is less than five bushels, they are not significantly different from one another. If there is a "NS" for the LSD 10% value it means there was no real difference between any varieties or the trial was too variable to detect a real difference. The CV stands for coefficient of variation and is expressed as a percentage. The CV is a measure of variability in the trial. Large CVs mean that a large amount of variation could not be attributed to differences in the varieties or agronomic characteristic.

The NDSU Langdon Research Extension Center, in addition to its on-station research program, conducted variety research trials at several locations in 2017. Trial locations were at Cavalier, Park River, Pekin, and Cando. These locations are in cooperation with a local farmer, the NDSU Extension Service and the County Crop Improvement Association.

2017 Weather Summary

A record setting 31.52 inches of precipitation was recorded in 2016 breaking the previous record of 28.05 inches set in 1954. The 2017 growing season precipitation ranged from 59-95 percent of normal with an average of 75 percent of normal across the region. The excessive soil moisture in 2016 provided valuable subsoil moisture in 2017 when topsoil moisture was below normal. Fall recharge at Langdon for September through October 2016 was 6.09 inches or 2.79 inches above normal. Precipitation from November 2016 through March 2017 was 4.61 inches or 2.79 inches above normal. Snowfall for 2016-2017 was 50.4 inches, 17.1 inches above normal with most of that coming in December. Winter temperatures were 5.2° F above normal. With the saturated subsoil moisture conditions coming into spring, the below normal precipitation in April and May allowed for timely planting of crops. Accumulated growing degree days averaged 8 and 46 above normal for corn and small grains, respectively, across NDAWN locations across the region. Disease levels were generally lower this year with the drier conditions. This along with the adequate rainfall and surplus subsoil moisture resulted in good to excellent yields of most crops across the region.

| 2017 Crop Management - Langdon | | | | | | |
|-------------------------------------|---------------|------------------------|------------|----------------|--------------|-------------|
| Field Trial | Previous Crop | Seeding Rate Unit/Acre | Yield Goal | Planting Date | Harvest Date | Row Spacing |
| Barley | soybean | 1.25 million pls | 100 bu | May 10 | Aug. 22 | 6 |

Fungicides were used in 2014-2015 but not in 2016-2017.

Severe stripe rust infections resulted in reduced yields in susceptible varieties in 2017.

HRWW Disease Summary, Langdon 2017

NS-No statistical difference between treatments.
 Harvest Date: September 29
 Tillage: Conventional

Protein adjusted to 16% moisture.
 Row Spacing: 6 inches
 Soil Type: Svea Barnes loam

Faba Beans are a long-maturing, cool season, annual legume that grow best under moist conditions. The current recommended seeding rate for Faba Beans is 4 seeds per square foot. Faba Beans have very large seeds often requiring a seeding rate of 3-4 bushels per acre, depending on the seed size. The research objective of this trial was to help determine the optimum seeding rate for our region. The lowest seeding rate had the lowest yield for both varieties. There were no significant differences in yield between the seeding rates 4 and 5 or 5 and 6 seeds/ft² for the varieties Boxer and Tabasco. The 2 year average indicated yield increasing numerically as seeding rates increased for both varieties. Most of the other significant differences between agronomic traits occurred between varieties.

¹DAP-Days after planting. ²Use to compare means within each variety.

Harvest Date: For May 9 and 20 seeding dates - Sept. 29. For May 30 and June 9 seeding dates - Oct. 20.

Row Spacing: 6 inches, Previous Crop: Durum Wheat, Tillage: Conventional, Protein: Adjusted to 16% moisture.

Experimental Design: Split-Plot, A (-) in the LSD box indicates there was no significant interaction between seeding rate and date and LSD's were calculated for variety and seeding date means averaged over treatment effect.

Faba Beans are a long-maturing, cool season, annual legume that grow best under moist conditions which need to be planted early to obtain higher yields. The objective of this trial was to determine the optimum seeding date for our region. Differences occurred between the two varieties for many agronomic traits. Both varieties responded similarly to seeding date for most agronomic traits and this resulted in few variety x date interactions. Boxer had a higher yield at the May 9 and 20 seeding date but had similar yields to Tabasco at the May 30 and June 6 planting dates. The two year average indicates the first two planting dates have the greatest yield potential.

Seeding Date, Variety, and Seed Treatment Influence on Industrial Hemp Performance in North Dakota-2017

NDSU Langdon Research Extension Center

Bryan K. Hanson¹, Burton L. Johnson², Travis W. Hakanson¹, Lawrence E. Henry¹, and Venkat Chapara¹.

¹North Dakota State University Langdon Research Extension Center, Langdon, ND; ²North Dakota State University, Plant Sciences, Fargo, ND.

Industrial hemp (*Cannabis sativa* L., THC level of 0.3% or less) can only be grown in North Dakota through the North Dakota Department of Agriculture pilot program or by institutions of higher education as stated in the 2014 farm bill. It has been over 70 years since industrial hemp has been raised in North Dakota. The NDSU Langdon Research Extension Center began conducting industrial hemp variety evaluations in 2015. To gain a better understanding of hemp production in North Dakota, common production practices, such as seeding dates, need to be investigated. Pure live seedling emergence (PLSE) of industrial hemp is lower, and often substantially lower, than for wheat, soybean, and corn and most other agronomic crops where 85% or greater PLSE is common and expected under average to good growing conditions. Fungicide seed treatments are a cost effective, common practice for improving PLSE in crops, and they become more important when stand establishment conditions are less than ideal. There are no labeled fungicide seed treatments currently available for industrial hemp in the USA. The objective of this study was to evaluate seeding date, variety and seed treatment effects on industrial hemp stand establishment, grain and fiber dry stalk yield and other agronomic traits.

Materials and Methods

Industrial hemp varieties utilized for this study are listed in Table 1. Seeding dates for the study were May 20, June 1 and June 12. The seeding rate was 12 pure live seeds/ft² and was adjusted for germination and 1000 kernel weight (kwt) with an additional 25 percent added to allow for seedling mortality. Planting depth was one-half inch. Plot size was 21 feet long x 4 feet wide and consisted of four 12 inch spaced rows. The experimental design was a randomized complete block split-plot design with four replications. The main treatment plot was seeding date and subplots were a factorial arrangement of variety and seed treatment. Seed treatments were Metalaxy (3 fl oz/100 lbs. of seed), Metalaxy+Ipconazole (1 fl oz/100 lbs. of seed) and the untreated check. The previous crop was soybeans. Total soil nitrogen from the soil test, applied and soybean N credit was equal to 160 lbs./a. Phosphorous soil test results indicated 21ppm. The fiber dry stalk yield harvest dates were August 8, 22, and 31 for the May 20, June 1 and June 12 seeding dates, respectively. Mortality was equal to 100 minus PLSE where PLSE refers to the percent of live seeds that produced a seedling. Fiber harvest consisted of one linear 10-foot row cut from each plot. The plant samples were air-dried and leaves were removed prior to weighing to determine dry stalk yield. Fiber yield and plant height were only determined on the untreated check plots. Grain harvest occurred on September 13 for all seeding dates. Industrial hemp is day-length sensitive and flowering occurs at about the same time period every summer regardless of the seeding date. A small plot combine was used to harvest the plots. Samples were dried and then processed to determine grain yield, test weight and 1000 kwt. Plant samples of all varieties, which included leaves and flowering heads, were sent for laboratory analysis of THC. All samples tested less than the 0.3% THC limit for industrial hemp classification.

Table 1. Industrial hemp varieties and characteristics for the Langdon 2017 trial.

| Variety | Country | Company† | Type | Purpose |
|---------|---------|----------|------------|---------|
| Katani | Canada | HGI | Dioecious | Grain |
| Delores | Canada | PIHG | Monoecious | Dual |

†HGI (Hemp Genetics International)
PIHG (Parkland Industrial Hemp Growers)

- Dual purpose varieties are bred to be used for both grain and fiber production and are generally taller.
- Dioecious varieties have separate male and female plants.
- Monoecious varieties have separate male and female flowers on the same plant.
- Plant height is an important consideration in determining end use of the crop. Shorter varieties tend to have less fiber and are more suited to grain production.

Results and Discussion

The sources of variation for the various treatments and their interactions are presented in Table 2.

Stand Establishment

Significant differences occurred for stand density, PLSE, and mortality for seeding date and seed treatment. Stand density and PLSE was greater for the May 20 seeding date compared to the June 1 and 12 seeding date. Seedling mortality was higher at the two later seeding dates (Table 3). Pure live seed emergence averaged 78% across seeding dates in 2017. This value is comparable to conventional crops such as wheat, soybeans and corn and is approximately two to three times (or more) greater than previous industrial hemp studies at the Langdon REC in 2015 and 2016. Rainfall of 2.55 inches during the first two weeks of June may have contributed to wet soil conditions that reduced stand density for seeding dates of June 1 and June 12 compared to the May 20 seeding where rainfall was only 0.87 inches from May 1 to May 22 (NDAWN). In 2015 soil crusting after planting on June 5, and saturated soil conditions after planting on June 20, 2016 reduced PLSE that ranged from 3 to 9% and 28 to 36%, respectively (Johnson et al., 2016). Stand density was 1.5 plants/ft² higher and PLSE 10% greater for the Metalaxyl + Iponazole seed treatment compared to the check (Table 4). Seedling mortality was lower for the Metalaxyl + Iponazole seed treatment compared to the check while the Metalaxyl treatment was similar to both the Metalaxyl + Ipcconazole and the check treatments.

Grain and Fiber Stalk Yield

Grain yield was 18% lower at the June 12 seeding date compared to the average yield of seeding dates of May 20 and June 1 (Table 3). Yield response to seeding dates was similar in trials conducted in Manitoba, Canada in 2014 and 2015. (Kostuik et al, 2014 and McEachern et al., 2015). Katani and Delores produced nearly identical grain yield when averaged across seeding dates and seed treatments (Table 5). Although stand density, PLSE, and mortality were significantly affected by seed treatments, there was no effect on grain yield (Table 4). Fiber dry stalk yield was significantly greater at the May 20 and June 1 seeding dates compared to the June 12 seeding date with the taller variety, Delores, having significantly higher yields (Tables 3 and 5).

Test Weight, 1000 KWT, and Plant Height

Variety differences occurred for test weight, 1000 kwt, and plant height, and varied among seeding dates resulting in a variety x seeding date interaction (Table 2). The differences were small and only the main effects of seeding date and variety are reported. The variety Katani had significantly lower 1000 kwt compared to Delores with no differences in 1000 kwt occurring among seeding dates (data not shown). Katani had a higher test weight than Delores while the May 20 and June 1 seeding dates had a significantly higher test weight compared to the June 12 seeding date (Table 4 and 5). Plant height averaged across the three seeding dates for Delores and Katani was 89 and 65 inches, respectively (data not shown).

Table 2. Sources of variation (SOV) and significant F-tests for industrial hemp traits evaluated at Langdon, ND, in 2017.

| SOV | Stand density | PLSE | Mortality | Test weight | 1000 kwt | Grain yield | Fiber dry stalk yield | Height |
|--------------|---------------|------|-----------|-------------|----------|-------------|-----------------------|--------|

| LSD (0.05) | 1.2 | 6 | 6 | 209 | 0.3 | 693 ¹ |
| LSD (0.10) | | | | | | |

Table 4. Industrial hemp stand density, pure live seed emergence, mortality and grain yield for three seed treatments at Langdon, ND in 2017.

| Seed Treatment | Stand density Plants/ft ² | PLSE % | Mortality % | Grain yield lb/a |
|-----------------------|-----------------------------------------|-----------|----------------|---------------------|
| Metalaxy | 12.3 | 77 | 23 | 1733 |
| Metalaxy + Ipconazole | 13.3 | 83 | 17 | 1873 |
| Check | 11.8 | 73 | 27 | 1801 |
| LSD (0.05) | 1.2 | 7 | 7 | ns |

Table 5. Industrial hemp variety effect on 1000 kwt, test weight, and grain and fiber dry stalk yield at Langdon, ND in 2017.

| Variety | 1000 kwt g | Test weight lb/bu | Grain yield lb/a | Fiber dry stalk yield lb/a |
|------------|---------------|----------------------|---------------------|-------------------------------|
| Katani | 15.4 | 42.0 | 1783 | 3021 |
| Delores | 19.0 | 40.9 | 1799 | 7271 |
| LSD (0.05) | 0.8 | 0.3 | ns | 621 |

Conclusions

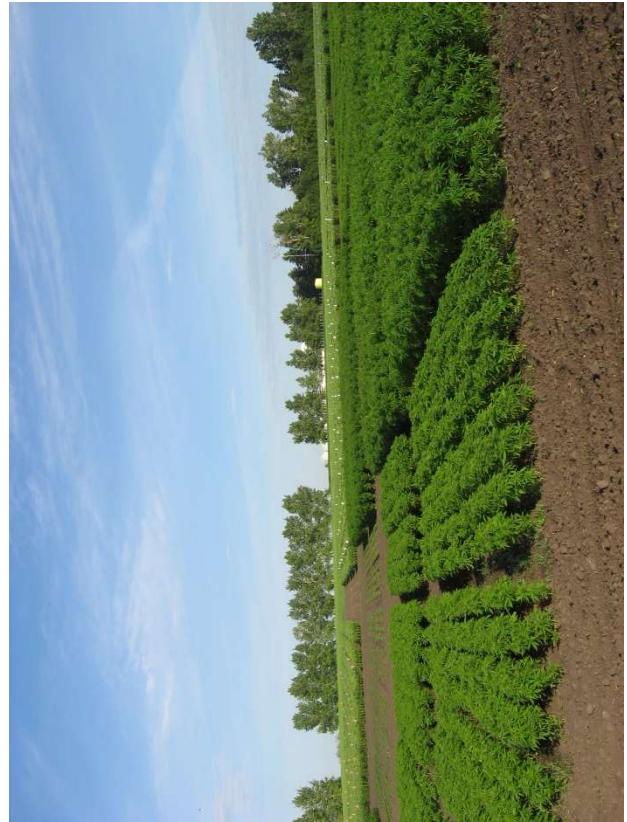

- Seeding date influenced stand density, PLSE, mortality, and grain and fiber dry stalk yield.
- The late seeding date resulted in reduced grain yield; however, seed treatment did not affect grain yield.
- Seed treatment with Metalaxy + Ipconazole improved stand density and PLSE, and reduced mortality, compared with the untreated check.
- Industrial hemp PLSE, mortality and stand establishment are sensitive to soil crusting and wet soil conditions.
- Live seed mortality is often greater for industrial hemp than commonly grown agronomic crops and requires careful grower management regarding planting date, seeding depth, and seed quality.

Industrial Hemp Variety Performance in North Dakota - 2017

NDSU Langdon Research Extension Center

Bryan K. Hanson¹, Burton L. Johnson², Travis W. Hakanson¹, Lawrence E. Henry¹, and Venkat Chapara¹.

¹ North Dakota State University Langdon Research Extension Center, Langdon, ND; ² North Dakota State University, Plant Sciences, Fargo, ND.

An industrial hemp variety trial (*Cannabis sativa* L., THC level of 0.3% or less) was conducted at the NDSU Langdon Research Extension Center. The objective of this study was to screen varieties (Table 1) from various sources, monitor and record plant growth and development, determine grain and dry stalk yield, note pest incidence, and record agronomic traits. Variety trials were previously conducted in 2015 and 2016. The 2015 trials were the first industrial hemp evaluations in North Dakota in over 70 years, and provided grain and fiber yield for Canadian and French varieties. The 2016 trial was lost due to herbicide drift, replanted and lost again to saturated soil conditions.

Table 1. Industrial hemp varieties and characteristics for the Langdon 2017 trial.

| Variety | Country | Company† | Type | Purpose |
|---------|---------|----------|------------|---------|
| CRS-1 | Canada | HGI | Dioecious | Grain |
| CFX-1 | Canada | HGI | Dioecious | Dual |
| CFX-2 | Canada | HGI | Dioecious | Grain |
| Grandi | Canada | HGI | Dioecious | Grain |
| Katani | Canada | HGI | Dioecious | Grain |
| Picolo | Canada | HGI | Dioecious | Grain |
| Canda | Canada | PIHG | Monoecious | Dual |
| Delores | Canada | PIHG | Monoecious | Dual |
| Joey | Canada | PIHG | Monoecious | Dual |
| X-59 | Canada | Terramax | Dioecious | Grain |

†HGI (Hemp Genetics International)
PIHG (Parkland Industrial Hemp Growers)

- ▲ Dual purpose varieties are bred to be used for both grain and fiber production.
- ▲ Dioecious varieties have separate male and female plants.
- ▲ Monoecious varieties have separate male and female flowers on the same plant.
- ▲ Plant height is an important consideration in determining end use of the crop. Shorter varieties tend to have less fiber and are more suited to grain production.
- ▲ Dual purpose varieties are generally taller.

Materials and Methods

Seeding date was June 1 with plants emerging five to six days later. The seeding rate was 12 pure live seeds/ft² and was adjusted for germination and 1000 kernel weight (kwt) with an additional 25 percent added to allow for seedling mortality. Planting depth was one-half inch. Plot size was 21 feet long x 4 feet wide and consisted of four 12 inch spaced rows. The experimental design was a randomized complete block with four replications. Previous crop was soybeans. The fiber dry stalk yield harvest date was August 8. Fiber harvest consisted of one linear 10 foot row cut from each plot. The plant samples were air-dried and leaves were removed prior to weighing to determine dry stalk yield. Grain harvest occurred on September 13. A small plot combine was used to harvest the plots. Samples were dried then processed to determine yield, test weight and 1000 kwt. Plant samples of all varieties, which included leaves and flowering heads, were sent for laboratory analysis of THC. All samples tested less than the 0.3% THC limit for industrial hemp classification.

Results and Discussion

There were no significant differences in pure live seed emergence (PLSE) among the varieties tested (Table 2). Pure live seed emergence values in 2017 were approximately two to three times (or more) greater than the previous four industrial hemp studies at the Langdon REC, in 2015 and 2016, where PLSE ranged from 3 to 61%. There were significant differences among varieties for seedling mortality that ranged from 20 to 41%. Seed/seedling mortality for traditional crops such as wheat, corn, and soybean commonly ranges from 10 to 15% under good/average conditions. Varieties CFX-1 (41%) and Picolo (35%) had the highest seedling mortality but final plant stand were not different among varieties and ranged from 9.5 to 12.9 plants/ft², which was close to the target plant population of 12 plants/ft². Fiber dry stalk yield was greatest for the dual purpose varieties which also had the greatest plant height and included the varieties CRS-1, Canda, Delores, and Joey. Canda, Delores, and Joey had significantly higher 1000 kwt compared to other varieties while X-59, Picolo, Katani, and Grandi were the highest test weight varieties. Yields of industrial hemp varieties were excellent and ranged from 1685 to 2052 lb/a. Grain yield for Canadian industrial hemp varieties in 2015 ranged from 632 to 1363 lb/a. Sclerotinia Stem Rot (White Mold), common in canola, dry bean and sunflower was observed in the trial but was at a very low incidence level.

Table 2. Grain and fiber yield and various agronomic traits of Canadian industrial hemp varieties.

| Variety | PLSE ¹ (%) | Seedling Mortality (%) | | | Plant Stand (ft ²) | Plant Height (inches) | Yield (lb/a) | KWT (g) | Test Weight (lb/bu) | Grain Yield (lb/a) | Grain Yield 2 yr Avg. (lb/a) |

¹ Pure live seed emergence

² 2015 and 2017

Conclusions

- The industrial hemp varieties tested appear to be suitable to the Langdon region of North Dakota.
- Seed mortality is an important issue in hemp production and not well understood and requires further research for improvement.
- Additional studies to identify superior varieties plus other crop production practices are needed.

Increased Spread of Clubroot to New Fields in Cavalier County

Project Title: Survey and Creating Awareness on Identification and Management Plan of Clubroot on Canola in Northeastern North Dakota

Survey done by: Venkat Chapara, Lesley Lubenow and Naeem Kalwar

A two-year survey program has been conducted in seven counties of northeastern North Dakota to determine the spread of clubroot on canola.

Survey Procedure: Clubroot scouting was done by visually inspecting canola crop roots. The disease survey was conducted in seven northeastern counties in North Dakota. Counties included were Pembina, Walsh, Nelson, Ramsey, Towner, Rolette and Cavalier. County selection was done on hypothesis of clubroot propagules movement in all directions through equipment, soil or water to neighboring counties of Cavalier. In each county, one field in every 2,500 acres was selected and scouted. GPS coordinates were gathered to identify the positive fields with intent to keep monitoring for future research. In all, a minimum of 5-10 fields per county were targeted for scouting. The survey was done in two phases.

1st phase:

In the growing season, stems were sampled from distinct patches of diseased or prematurely senescing plants in the field. Patches visible from the edge of the field were checked by digging out plants and observing the roots for symptoms of clubroot.

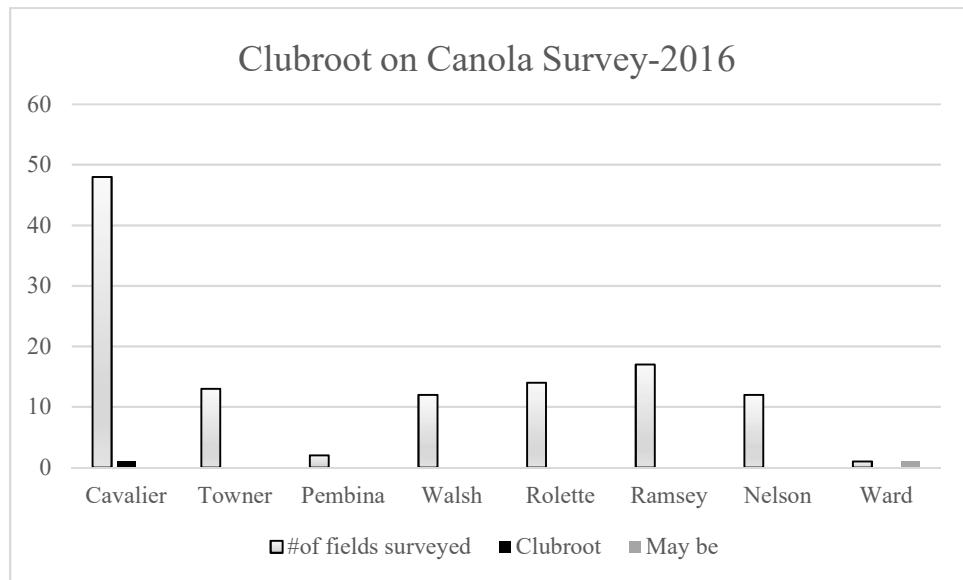

2nd phase:

After swathing:

The methodology of scouting at swathing was based on the methodology followed in Canada by the Alberta Agricultural and Rural Development (AARD) for clubroot disease survey. AARD indicated that the incidence of clubroot is more in the field entrances. The survey was done from the field main entrances. From the main entrance in the field, the survey group walked along in a "W" pattern by stopping at 10 spots and uprooting 10 consecutive stems from the ground at each spot. Excess soil was shaken off. Roots were visually examined for presence of galls. At sample sites where infection was observed or suspected, root specimens with galls, along with soil, were double bagged and labeled with the field location. Infected roots and soil samples from possible fields with clubroot were submitted to Dr. Luis Del Rio's laboratory for molecular confirmation and pH determination, respectively. Each sampling point was separated by 100 meters. In all, roots of 100 stems were evaluated for the presence of clubroot and incidence was noted. Disease severity was done by using a rating scale.

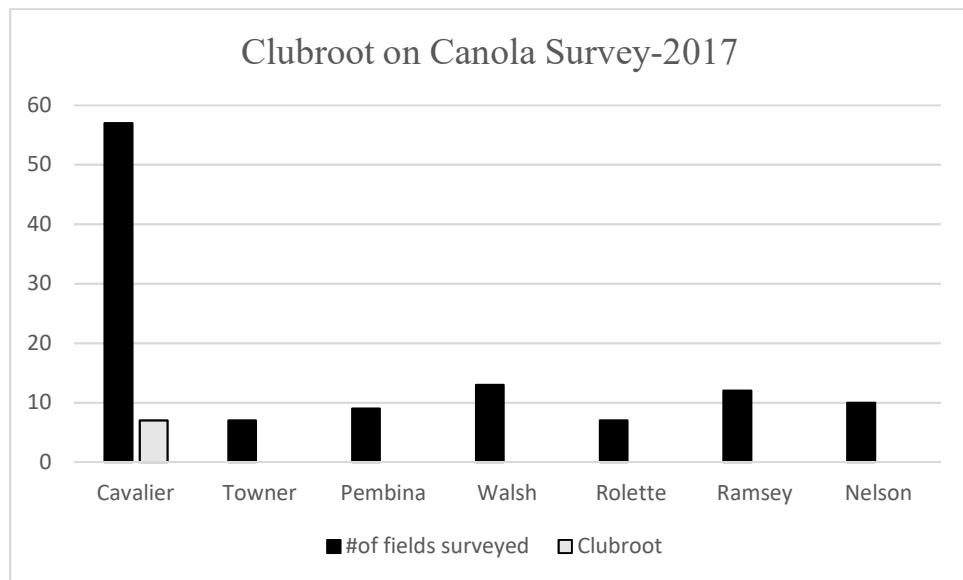

Clubroot Rating Scale: In fields where clubroot is found, roots within the 1 m² area at each sampling location were dug from the soil and rated on a four-point scale, where: 0 = no galls, 1 = a few small galls, 2 = moderate galling and 3 = severe galling.

Figure 1: Fields surveyed in 2016 for prevalence of clubroot over 8 counties.

In 2016, 119 fields in eight counties were surveyed by our research group (Figure 1). One positive clubroot field has been identified in Cavalier County. The level of clubroot incidence in the positive clubroot field was 99% with maximum severity of root galling (Rating Scale range 3). One field in Ward County (Figure 1) was found with severity rating of 2. The molecular analysis (Polymerase Chain Reaction) report from Dr. Luis Del Rio indicated negative to clubroot. The clubroot like symptoms on canola root can be attributed to root hybridization in canola, which is often confused with clubroot symptoms.

Figure 2: Fields surveyed in 2017 for prevalence of clubroot over 8 counties.

In 2017, 115 canola fields were surveyed and seven fields have been identified as potentially infected with clubroot. Samples were sent for molecular diagnosis to Dr. Luis Del Rio's laboratory in Fargo.

Determination of Soil pH: Soil samples from clubroot positive fields and from the clubroot suspected fields were collected as per the procedure described by the Manitoba Agriculture, Food and Rural Development (MAFRD), Canada. The soil samples were submitted to the NDSU soil-testing laboratory in Fargo and the soil pH is presented in Table 1.

Table 1: Latest pH of soil samples collected in each county from canola fields during the 2017 clubroot survey.

| Depth of soil sample | pH | GPS Coordinates | | | County | Clubroot Response |
|----------------------|------|-----------------|-------------|--|----------|-------------------|
| | | N | W | | | |
| 0-6 | 6.46 | 48. 54. 612 | 98. 04. 805 | | Cavalier | Negative |
| 0-6 | 6.96 | 48. 47. 405 | 98. 12. 758 | | Cavalier | Negative |
| 0-6 | 7.12 | 48. 52. 560 | 97. 17. 661 | | Pembina | Negative |
| 0-6 | 6.45 | 48. 57. 790 | 97. 36. 738 | | Pembina | Negative |
| 0-6 | 7.18 | 48. 26. 733 | 98. 20. 928 | | Ramsey | Negative |
| 0-6 | 7.06 | 48. 42. 256 | 99. 48. 990 | | Rolette | Negative |
| 0-6 | 6.85 | 48. 53. 596 | 99. 39. 401 | | Rolette | Negative |
| 0-6 | 6.97 | 48. 48. 909 | 99. 18. 456 | | Towner | Negative |
| 0-6 | 7.26 | 48. 50. 908 | 99. 09. 096 | | Towner | Negative |
| 0-6 | 7.19 | 48. 28. 808 | 97. 43. 905 | | Walsh | Negative |
| 0-6 | 8.13 | 48. 34. 342 | 98. 12. 243 | | Walsh | Negative |

*All the positive clubroot samples have soil pH ranging from 4.5 to 5.7.

Clubroot on Canola Awareness Meetings:

Clubroot on canola awareness meetings were conducted across the area; five in Cavalier, two in Pembina, two in Walsh, and one in Towner County during the growing season. The survey report were sent at the end of the season to growers and other commodity groups. Ramsey and Nelson counties were covered in the Lake Region Roundup meeting on January 4, 2017. One meeting in Rolette County was conducted the last week of March. The same number of meetings will be conducted in 2018-2019.

Outcome: Meetings on creating awareness of clubroot on canola and its management in various counties showed measurable improvement in growers understanding the disease clubroot on canola. Several growers came forward to cooperate in clubroot management research. Phone calls in the growing season and requests for personal visits to the grower's fields with clubroot concerns increased. Knowledge of crop rotation, planting resistant varieties and sanitation implementation were the major topics and will be considered for future canola production in the northeastern North Dakota region.

Agriculture extension agents who helped in the survey and in conducting clubroot awareness meetings in respective counties.

Evaluation of Various Chemicals, Cruciferous Hosts and Canola Cultivars to Manage Clubroot on Canola in Field Conditions

Venkat Chapara

Objective 1: Evaluating the effects of adding fungicides and pH-altering soil amendments to soil of clubroot on canola incidence and severity in field conditions.

Nine treatments consisting of fungicides and various compounds (Table 1) that can alter pH or other characteristics of the soil were amended to soil and were compared with non-treated checks to evaluate their efficacy against clubroot pathogens under field conditions.

Treatments of wood ash, pellet lime, beetlime and gypsum were applied seven days before planting into the soil at a depth of three to four inches and thoroughly mixed in soil with a rototiller.

Whereas, the rest of the treatments were applied just before planting into the soil at a depth of three to four inches thoroughly mixed in the soil with a rototiller.

Table 1: List of products that were amended in soil to manage clubroot on canola

| PRODUCT | TRADE NAME | DOSAGE |
|----------------------|---------------|---------------------------------------------------|
| CYAZOFAMID | Ranman | 7.5 l/ha |
| FLUAZINAM | Allegro | 2000 g/ha |
| PCNB | Terrachlor | 237 ml/plant as a drench |
| WOOD ASH | Fly Ash | 7.5 t/ha |
| CALCIUM CARBONATE | Pellet | 7.5 t/ha |
| BEET LIME | Lime | |
| GYPSUM | Versa Lime | 15 t/ha |
| NANO-PARTICLE | Gypsum | 7.5 t/ha |
| | Zn | 500mg |
| | | Zn |
| NON-IONIC SURFACTANT | Aqua-Gro 2000 | 10g/m Incorporated into rows just before planting |
| NON-TREATED | Check | |

Variety: DKL 30-42 RR

Plot Size: 3 ft. x 5ft.

Planted on: 6/5/2017 (Hand planted after thorough tillage with a rototiller.)

Field Design: Randomized Complete Block Design (RCBD) with four replications.

Clubroot Evaluated on: 7/31/2017

Rating scale used: Clubroot rating scale: 0 = no galling; 1 = a few small galls (small galls on less than 1/3 of roots), 2 = moderate galling (small to medium-sized galls on 1/3 to 2/3 of roots), 3 = severe galling (medium to large-sized galls on more than 2/3 of roots) (S.E. Strelkov).

Figure 1: Efficacy of fungicides and soil ameliorating products against clubroot incidence in field conditions.

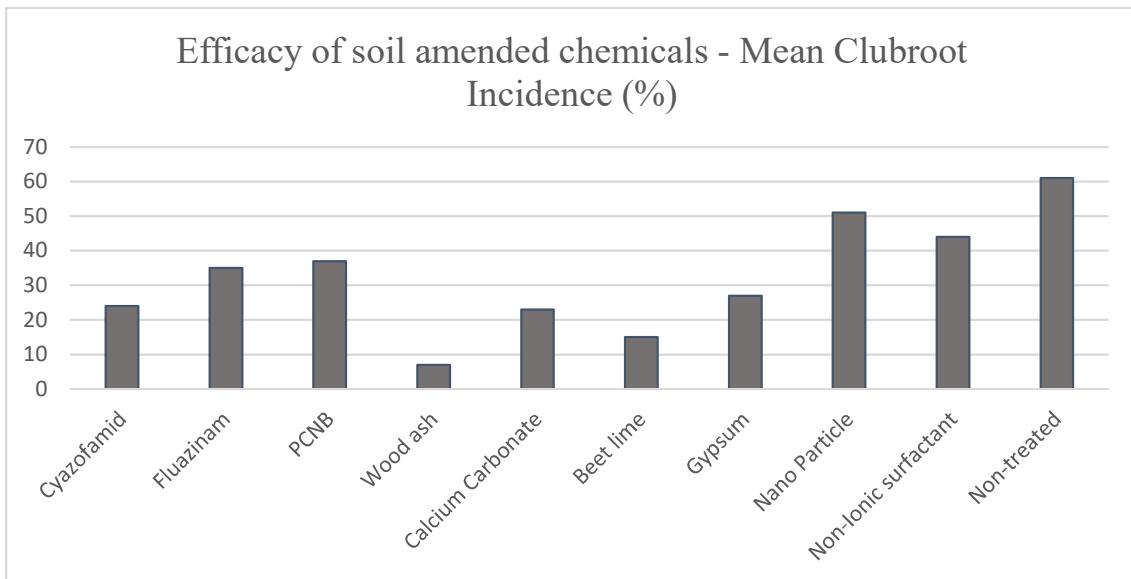

Figure 2: Efficacy of fungicides and soil ameliorating products against clubroot severity in field conditions.

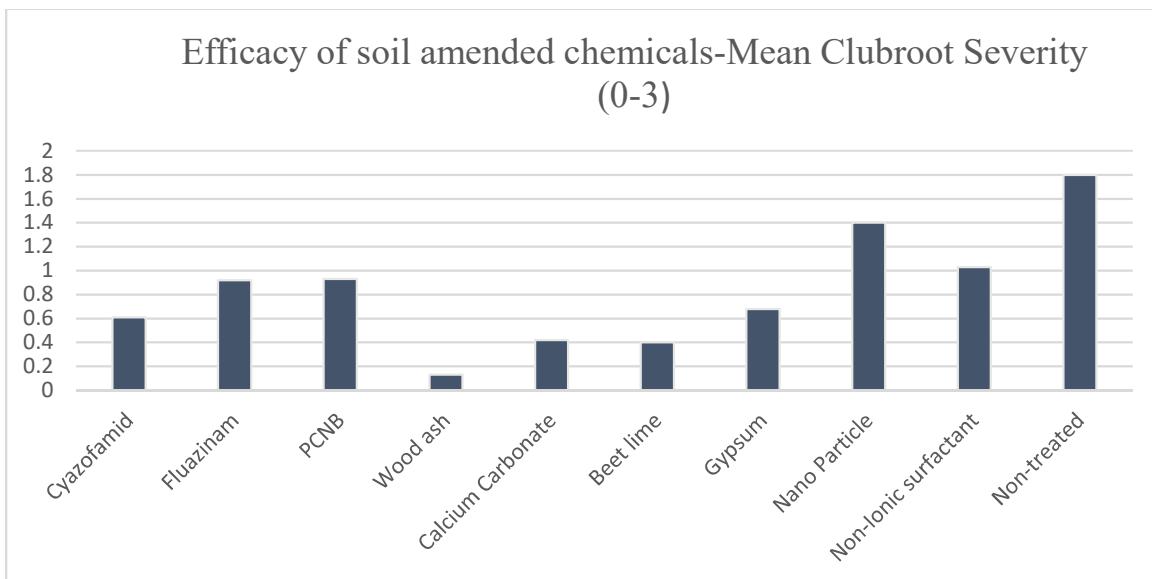

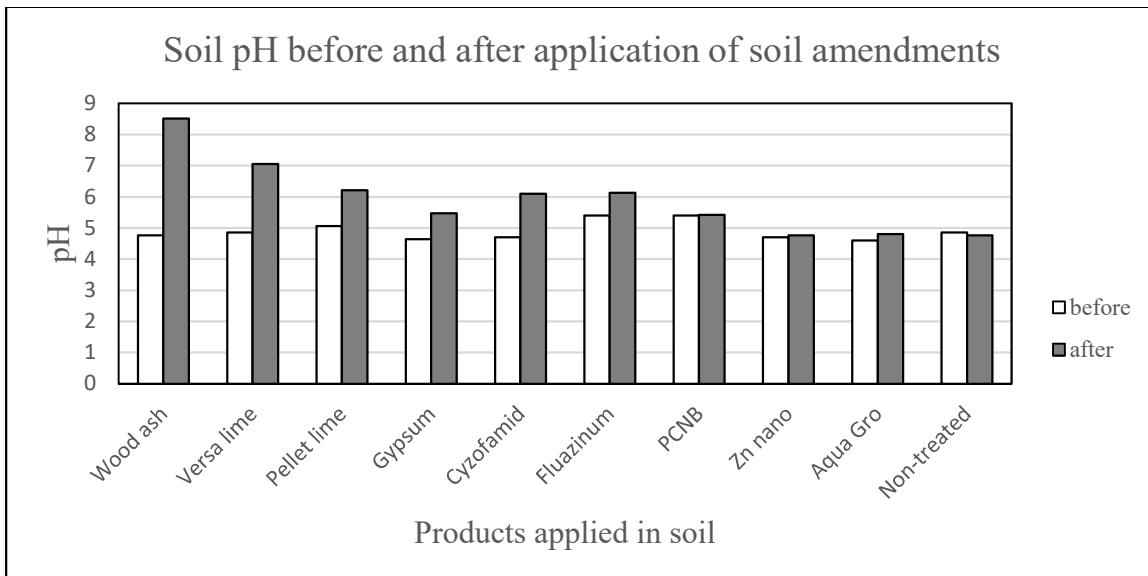

Figure 3: Soil pH before and after application of soil amendments to manage clubroot on canola.

Results: Significant differences in clubroot incidence and severity were observed in wood ash treatment followed by beet lime and calcium carbonate than the other treatments used. However, results of wood ash are debatable as the emergence was very poor in all four replications. In general emergence and growth of many crop plants cease at 8.5 pH. This could be one of the reasons for low emergence in wood ash treated plots. Beet lime (Versa lime) and calcium carbonate (Pellet lime) results are considerable. These results are worth testing for a few more seasons in field conditions. The pH changes from acidity to alkalinity of the soil in the treated plots after application of beet lime and versa lime can result in low clubroot disease incidence and severity.

Objective 2: Evaluating the symptoms caused by clubroot pathogen on various hosts of brassica family in field conditions.

Cruciferous host plants: Ten host plants from cruciferous family were planted

Plot Size: 3 ft. x 5ft.

Planted on: 6/5/2017 (Hand planted after thorough tillage with a rototiller.)

Field Design: Randomized Complete Block Design (RCBD) with four replications.

Clubroot Evaluated on: 7/31/2017

Figure 4: Mean clubroot incidence (%) on various cruciferous hosts.

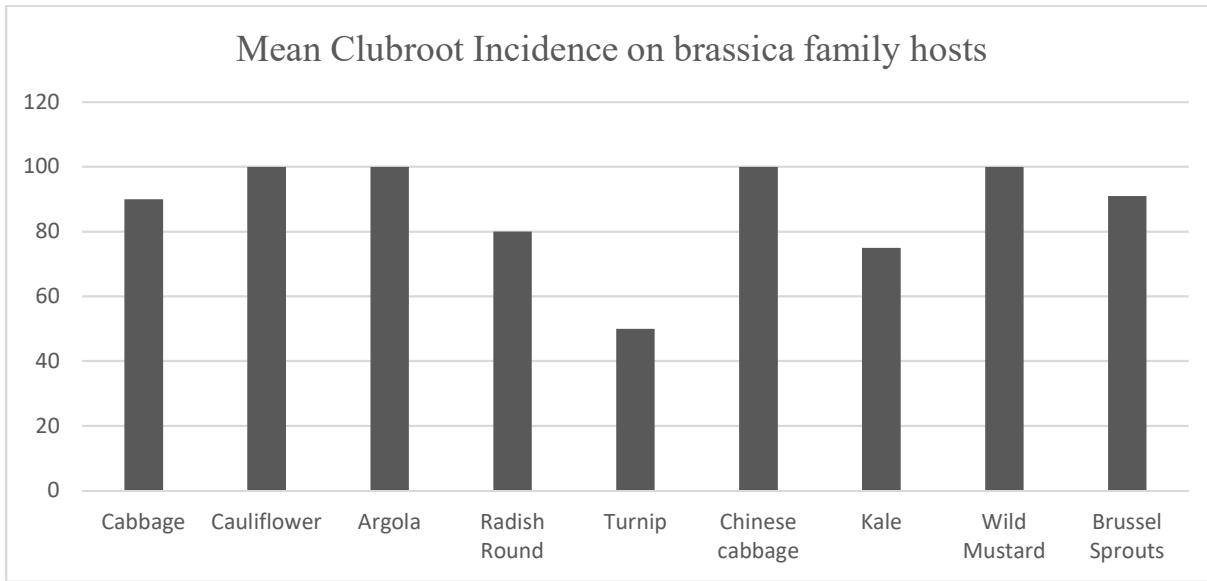

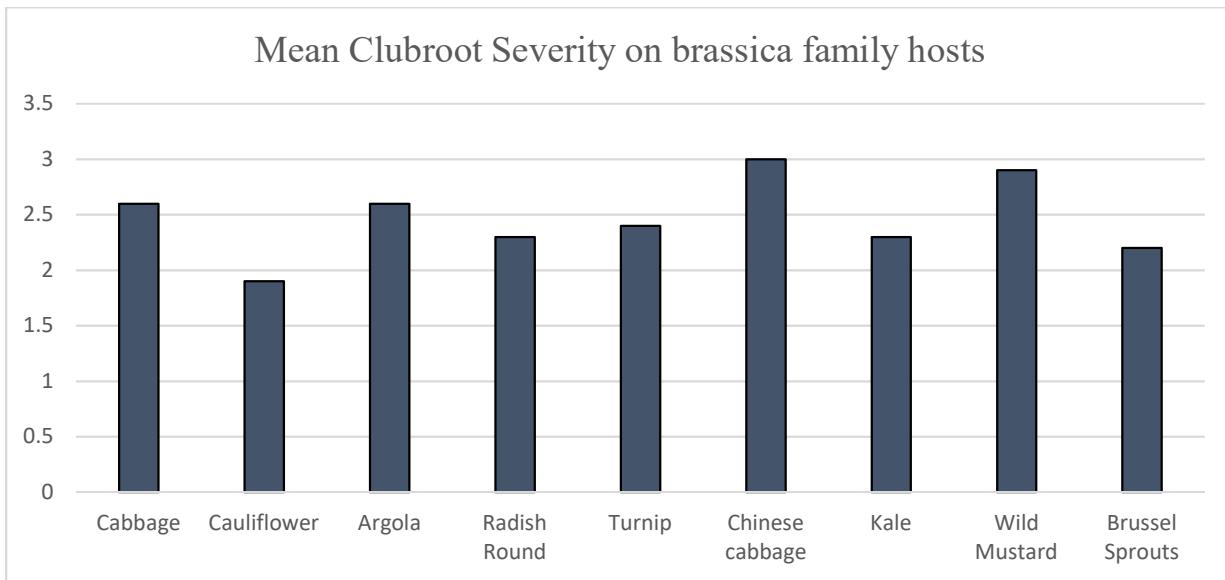

Figure 5: Mean clubroot severity (%) on various cruciferous hosts.

Results: Out of the ten cruciferous hosts planted, seeds of shepherd's purse did not germinate. The remaining nine host plants showed positive response to clubroot infection. The cruciferous host turnip had significantly less incidence of clubroot. More seasons of evaluations in field conditions are needed.

Objective 3: Evaluation of commercial canola cultivars against clubroot pathogen in field conditions.

Plot Size: 3 ft. x 5ft.

Nine commonly cultivated canola varieties have been planted along with an experimental line of canola (Table 2).

Table 2: Commonly cultivated canola varieties in Cavalier County.

| S.No | Cultivar | Clubroot | |
|------|-----------------------|-------------|--------------|
| | | Response | Source |
| 1 | DKL 30-42 | Susceptible | CHS |
| 2 | InVigor L252 | Susceptible | Grower |
| 3 | InVigor L233P | Susceptible | Grower |
| 4 | Integra 7150rr | Susceptible | Wilbur-Ellis |
| 5 | Integra 7257rr | Susceptible | Wilbur-Ellis |
| 6 | 45CS40 | CR | Pioneer |
| 7 | 45H33 | CR | Pioneer |
| 8 | InVigor L241C | CR | Bayer |
| 9 | Bayer Exptl. | CR | Bayer |
| 10 | Nexera 1022RR | CIR | Simplot |

Note:

CR: Clubroot resistant

CIR: Clubroot intermediately resistant

Planted on: 6/5/2017 (Hand planted after thorough tillage with a rototiller.)

Field Design: Randomized Complete Block Design (RCBD) with four replications.

Clubroot Evaluated on: 7/31/2017

Figure 6: Mean clubroot incidence (%) on various commercially available cultivars of canola.

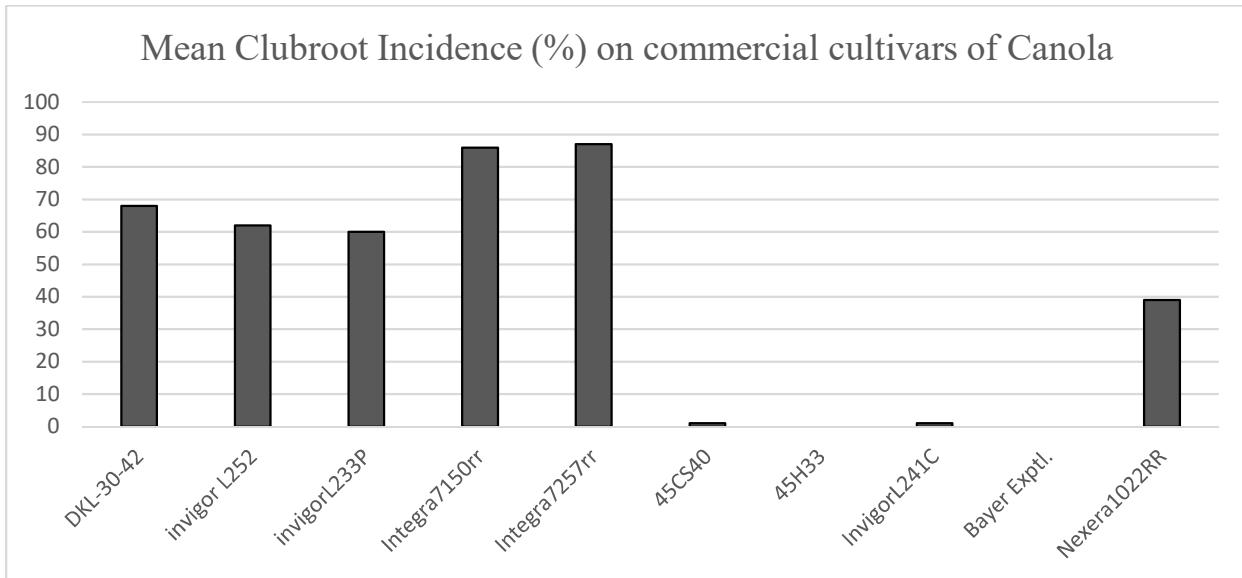

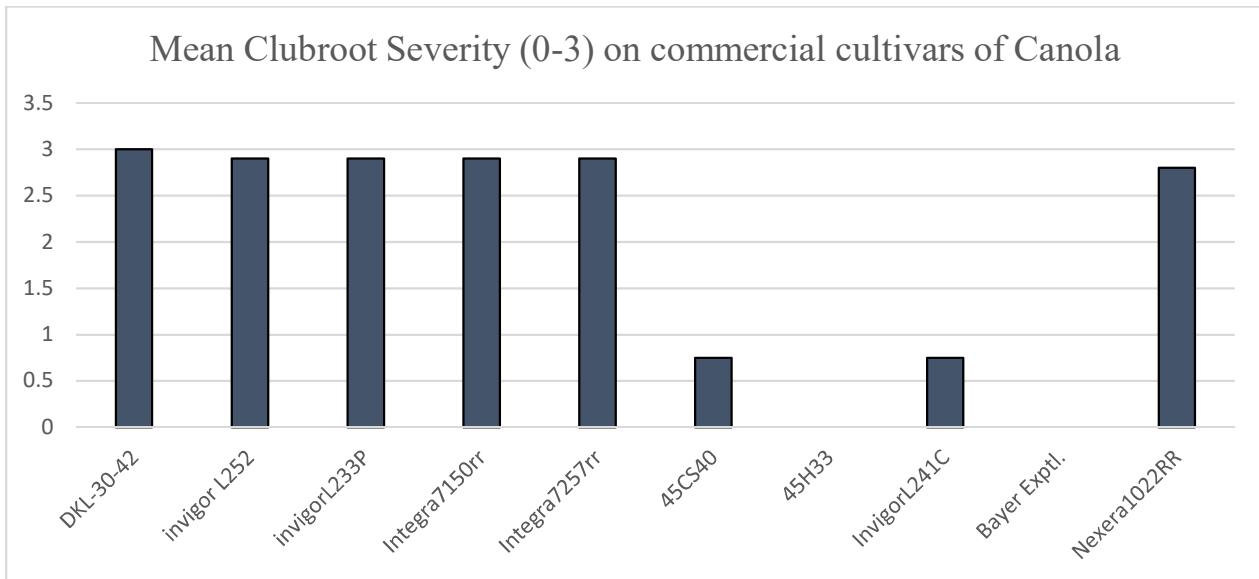

Figure 7: Mean clubroot severity (%) on various commercially available cultivars of canola.

Note: Bayer Experimental variety is now available as InVigor© L255P in North Dakota.

Results: Canola cultivars 45H33 and an experimental line of canola (InVigor© L255P) showed zero percent in clubroot incidence and severity followed by low incidence (1%) and severity (0.75%) in canola cultivars “45CS40” and “InvigorL241C” and were significantly different from the other varieties tested.

Additional commercial cultivars to this list will be very helpful to the growers.

Fungicide Evaluation to Manage White Mold in Canola

Amanda Arens and Venkat Chapara

The research trial was conducted at the Langdon Research Extension Center and was planted on May 19th 2017 with the canola variety “DKL 30-42 (Roundup Ready)” in a randomized complete block design and replicated four times. Canola production recommendations for northeast North Dakota from the North Dakota State University Extension Service were followed. The plot size was 5 ft. x 16 ft. long with a canola border between each plot. The trial was irrigated with an overhead sprinkler system set for 1 hour every day beginning one week before the start of bloom to 4 weeks after bloom to help increase disease infection levels. Fungicides were applied at 20% bloom using a CO₂-pressurized backpack style sprayer with a three nozzle boom (XR-8002) at 20 GPA and were repeated 8 days after first spray. The amount of white mold infection obtained in the research plots was natural. Fifty plants per plot were rated on a scale of 0-5 (where 1=superficial lesions or small branch infected; 2=large branch(es) dead; 3=main stem at least 50% girdled; 4=main stem girdled but plant produced good seed; 5=main stem girdled, much reduced yield). The levels of incidence and severity were recorded for each plant prior to swathing (August 18). A white mold disease severity index was calculated with weighted scale of incidence and severity ratings.

Table 1: Efficacy of commercially available fungicides in managing white mold and their influence on yield and test weight.

| Treatments | Dosage (Fl oz/A) | White Mold DSI* | Test Weight | |
|----------------|---------------------|--------------------|-------------|----------|
| | | | (lbs/A) | (lbs/bu) |
| Aproach + NIS | 9 | 0.03 | 3794 | 52 |
| Endura + NIS | 6 | 1.33 | 4086 | 52 |
| Proline + NIS | 4.3 | 0.28 | 4200 | 52 |
| Quash + NIS | 3 | 0.19 | 3968 | 52 |
| Topsin | 231(g/A) | 0.23 | 4372 | 52 |
| CHECK | Check | 1.46 | 3769 | 52 |
| Mean | | 0.59 | 4031 | 52 |
| CV (%) | | 59 | 14 | 0.76 |
| LSD | | 0.62 | 1014 | 0.7 |
| p-Value | | 0.0006 | NS | NS |

NIS: Non-Ionic Surfactant 0.25% V/V

DSI*: White Mold Disease Severity Index

NS: Non-Significant

The results indicate there were significant differences obtained among the fungicides tested and the non-treated check. More white mold DSI was observed in Endura and the non-treated check while Aproach was low. There were no significant differences among the treatments when yield and test weights were compared.

Management of Blackleg in Canola with Fungicides

Amanda Arens and Venkat Chapara

The research trial was conducted at the Langdon Research Extension Center and was planted on May 19, 2017 with the canola variety “DKL 30-42 (Roundup Ready)” in a randomized complete block design with four replications. Canola production recommendations for northeast North Dakota from the North Dakota State University Extension Service were followed.

The plot size was 5 ft. x 16 ft. long with a canola border between each plot. Two applications of fungicides were applied at the 2-4 leaf stage and 14 days after the first application using a CO₂-pressurized backpack style sprayer with a three nozzle boom (XR-8002) at 10 GPA. The level of blackleg was of natural infection. The severity of blackleg infection was evaluated on 100 plants averaged over four replicates after swathing on August 25. Individual plants were uprooted, cut through the basal part of the stem and scored on the percent of diseased tissue visible in the cross-section. The ratings were zero when no diseased tissue was visible in the cross-section, and 100 if the diseased tissue occupied 100 percent of the cross-section with significant constriction of affected tissues, drying of tissue and brittle or the plant was completely dead.

The results indicate there were no significant differences obtained among the variables tested when compared with that of the non-treated check except in yields. Yields of Proline treated plots are significantly different from the other treatments in the trial.

Table 1: Efficacy of commercially available fungicides in managing black leg and their influence on yield and test weight.

| Treatment | Dosage (Fl oz/A) | Application Timing | Black Leg | | Yield (lbs/A) | Test Weight (lb/bu) |
|----------------|---------------------|-----------------------|------------------|----------------|------------------|------------------------|
| | | | Incidence (%) | Mean Severity* | | |
| Non-treated | Check | Check | 36 | 0.48 | 2646 | 52 |
| Headline | 6 | 2-4 leaf+14DAA | 29 | 0.25 | 2385 | 52 |
| Priaxor | 6 | 2-4 leaf+14DAA | 21 | 0.34 | 2479 | 52 |
| Proline | 4 | 2-4 leaf+14DAA | 20 | 0.28 | 3121 | 52 |
| Mean | | | 27 | 0.34 | 2657 | 52 |
| CV (%) | | | 63 | 41 | 11 | 0.3 |
| LSD | | | 26 | 0.21 | 438 | 0.25 |
| p-Value | | | NS | NS | 0.01 | NS |

*Black Leg Mean Severity: was calculated by multiplying the category value (0-5)*actual severity (0.2,0.4,0.6,0.8,1.0), and summing, then dividing by the infected plant count.

NIS: Non-Ionic Surfactant was added at 0.25% V/V in all the fungicide treatments.

Management of Fusarium Head Blight in Spring Wheat Cultivars with Fungicides

Venkat Chapara, Amanda Arens, and Andrew Friskop

Objective: To evaluate the efficacy of fungicides in single and sequential applications to manage Fusarium head blight (FHB) in hard red spring wheat (HRSW).

Methods:

Location: NDSU Langdon Research Extension Center.

Experimental Design: Randomized complete block with split plot arrangement, four replications.

Previous crop: Soybean

Cultivars of HRSW tested: WB Mayville and SY Ingmar

Planting: 1.2 million pure live seeds/A planted on May 5, 2017. A border plot was planted between treated plots to minimize interference from spray drift.

Plot size: Seven rows at six inch spacing, 5 ft. x 20 ft., mowed back to 5 ft. x 16 ft.

Herbicides Applied: Axial XL (16.4 Fl. oz/A) + Huskie (15 Fl. oz/A) + Prowl H₂O (36 Fl. oz/A)

Inoculation: Plots were inoculated by spreading corn spawn inoculum at around boot stage (Feekes 9-10) at the rate of 300 g/plot.

Disease development: Supplemental moisture was provided by running overhead irrigation from Feekes 9 to 11.25 at the rate of one hour per day to create a conducive environment for FHB development.

Fungicide treatments: Fungicides were applied, with a CO₂-pressurized backpack sprayer with a three nozzle boom (XR-8002) and the water volume used was 20 GPA. Fungicide application was made at Feekes 10.51 (anthesis) on July 7 and repeated 4 days after the first spray (July 13, 2017). Refer to Table 1 for the treatments, dosages and application timings.

Disease Assessment: Data on FHB incidence was obtained by counting the number of heads showing FHB symptoms out of 50 heads. FHB head severity was rated using 0-100% scale on arbitrary 50 heads, excluding two outer rows. FHB index (Index) was calculated using formula: Index = (SEV*INC)/100.

Harvest: Plots were harvested on August 24 with a small plot combine and the yield was determined.

Data Analysis: Statistical analysis was done using SAS. Fisher's least significant difference (LSD) was used to compare means at $p(\alpha = 0.05)$. Actual means are presented in the table for simplicity of understanding.

Results:

The HRSW Cultivar “WB-Mayville” is significantly different from the cultivar “SY-Ingvær” in all the parameters tested in the current research trial. On the cultivar “WB-Mayville,” all the fungicide treated treatments are significantly different from both checks when compared with the parameters tested. Similarly, on the HRSW cultivar “SY-Ingvær” both the checks are significantly different than the fungicide treatments. The treatment Proline at anthesis and folicur at 4 days after anthesis has low FHB Index (0.03), and higher DON (4.9 ppm). Whereas, the treatment Prosaro at anthesis and 4 days after anthesis with FHB Index of 0.04 and lower DON (1.1 ppm) content when compared with all the treatments of the trial. However, there were no significant differences in yields, test weights, seed count, FDK parameters among the fungicide treatments and were significant to the non-treated inoculated and non-treated non-inoculated checks.

Table 1: Fungicides tested alone and in combinations on two HRSSW varieties at two application timings to manage Fusarium head blight and evaluation of their influence on yield and other grain characteristics: toxin (DON) content, FDK, and test weight.

| Treatments, Dosage and Application Time | Cultivar | Fusarium Head Blight Index | Bu/A | Yield lbs/bu | Test weight | Seed count # | Seed weight (g) | FDK (%) | DON (ppm) |

DETERMINING THE ECONOMIC RESPONSE OF SODIC SOILS TO REMEDIATION BY GYPSUM, ELEMENTAL SULFUR AND VERSALIME IN NORTHEAST NORTH DAKOTA ON TILED FIELDS

By

Naeem Kalwar (Extension Area Specialist/Soil Health)

INTRODUCTION:

Saline and sodic soils have been reported in North Dakota since the 1960s. NDSU Extension Bulletin No. 2 reported more than 1 million acres are affected by high salt levels, whereas, more than 2 million acres are said to have excessive levels of sodium (Salt Affected Problem Soils in North Dakota, Their Properties and Management by Gordon A. Johnsgard, reprinted in 1974). This is a result of high salt and sodium levels in the soil parent material and the underlying sodium-rich shale present in the bedrock below the soil sediments. Rising groundwater levels and resulting capillary rise of soil water leads to the accumulation of excessive soluble salts (salinity) and sodium (sodicity).

Saline soils will have excessive levels of soluble salts in the soil solution which are a combination of positively and negatively charged ions (for example, table salt; Na^+Cl^-). High levels of ions (positive and negative) from soluble salts restrict normal water uptake by plant roots, even when soils are visibly wet, resulting in drought-stressed plants ("osmotic effect").

Saline soils having higher levels of calcium (Ca^{2+}) based salts will have good structure. That happens as calcium (Ca^{2+}) ions encourage aggregation of soil particles called flocculation (clumping together), resulting in well-defined pores facilitating free water movement through the soil profile.

In contrast to saline soils, sodic soils are highly saturated with sodium ions (Na^+) at the soil cation exchange sites. High Na^+ levels compared to Ca^{2+} in combination with low salt levels can promote "soil dispersion," which is the opposite of flocculation. Soil dispersion causes the breakdown of soil aggregates, resulting in poor soil structure (low "tilth" qualities). Due to the poor soil structure, sodic soils have dense soil layers, resulting in very slow permeability of water through the soil profile. Due to poor soil structure, when wet, sodic soils will be gummy and may seem like they have "no bottom" to them, and when dry, they can be very hard.

OBJECTIVES:

Remediation of soil sodicity requires application of amendments that supply Ca^{2+} followed by salinity remediation practices of improving soil drainage and lowering the groundwater level. Ca^{2+} displaces Na^+ from the cation exchange sites and Na^+ moves into soil solution where it converts into a salt (Na_2SO_4) and leaches out with rainfall or irrigation.

An effective way to lower groundwater levels is to install a field tile drainage system. Since tiles are generally three to four feet below the surface, the efficiency of a tile drainage system depends upon the permeability of soil layers above the tiles. This requires analyzing soils for salts and Na^+ . In case of high Na^+ levels, not adding Ca^{2+} can render tiling ineffective. That could be achieved by sampling the areas in question and getting the samples analyzed by a soil laboratory. For detailed information on sampling for salts and Na^+ , please refer to the NDSU Publication: SF-1809; "Soil Testing Unproductive Areas". Another NDSU publication that provides detailed information regarding the suitability of soils for tiling is: SF-1617; "Evaluation of Soils for Suitability for Tile Drainage Performance".

Challenges for landowners considering tiling could be:

- 1. If the Na^+ levels are high in the soils they would like to tile?**
- 2. In case of high levels of Na^+ , what should they do first, tile or apply the amendments?**

In July 2014, the Langdon Research Extension Center (LREC) tiled a field that had excessive levels of Na^+ and moderately high levels of soluble salts. This consisted of 12 research plots with three replications. In order to replicate field conditions, the project site was tiled in July 2014 prior to starting sodicity remediation by applying soil amendments that are suitable and easily available to northeast North Dakota growers. Soil amendments were applied one-year after tiling in July and August of 2015.

The following objectives were set in order to achieve research goals.

- Can tiling be successful on sodic or saline-sodic soils prior to starting sodicity remediation?
- Comparing the relationship between varying water table levels and resulting soil salt and Na^+ levels.
- Analyzing water samples from the lift station, upstream and downstream for human and livestock health.

TRIAL LOCATION AND SITE DESCRIPTION:

This trial site is located at the NDSU Langdon Research Extension Center, Langdon, North Dakota. As per web soil survey, soil series are Cavour-Cresbard and Hamerly-Cresbard loams.

TRIAL DESIGN AND PLOT SIZE:

Trial design is a randomized complete block. Each plot is 325 X 80 feet.

METHODOLOGY:

Soil Chemical Analysis

Four feet deep soil samples in 12" increments from each plot were collected in September 2014, directly after tiling. Using the same protocol, site was sampled again in June 2016 (two-year after tiling and one-year after applying the amendments) and in June 2017 (three years after tiling and two years after applying the amendments). Each sampling activity included 48 soil samples (12 plots x 4 depths = 48 samples). All samples were analyzed for Salts (Electrical Conductivity or EC) and sodium (Sodium Adsorption Ratio or SAR), pH, calcium carbonate equivalent (CCE), bicarbonate (HCO_3^-), chlorides (Cl^-), sulfates (SO_4^{2-}), saturation percentage, calcium (Ca^{2+}), magnesium (Mg^{2+}), sodium (Na^+), potassium (K^+) and nitrate-nitrogen (NO_3-N^-) for 0-4 feet depths. Soil phosphorus (P) and organic matter percent (O.M. %) were analyzed at the 0-2 feet depths. In addition, cation exchange capacity (CEC) was measured for the first foot.

Weekly Groundwater Level Measurements

Groundwater levels were measured on a weekly basis in 2015, 2016 and 2017 from May-October through the seven-foot deep observation wells installed in each plot in 2015.

Water Sample Analysis

Water samples were collected from the lift station, upstream and downstream in fall-2015 and May, July and September of 2016 and in May and August of 2017. The samples were analyzed by the ND Department of Health for Group 2 complete mineral chemistry, Group 7 trace metals and Group 30 nutrients.

Treatments and Replications

Soil amendment rates were calculated to bring the SAR (SAR-final) numbers to an acceptable level of 3 in the first foot. This was done by deducting three from the actual SAR numbers (SAR-initial). SAR-final values were converted into Exchangeable Sodium Percentage (ESP) by using the formula given in "Diagnosis and Improvement of Saline and Alkali Soils" (USDA Salinity Laboratory Staff, Agriculture Handbook No. 60, 1954, Page-26). Gypsum rates were then calculated by using a standard formula given in the same handbook (page-49). For each ton of 100% pure gypsum, 0.19 ton of 100% pure elemental sulfur was applied (Reclaiming Saline, Sodic, and Saline-Sodic Soils. University of California, ANR Publication 8519, August 2015). Considering the very low solubility of VersaLime, for each ton of 100% pure gypsum, three tons of VersaLime were applied. Differences in

amendment purities were compensated by using the formula given in "Reclaiming Sodic and Saline/Sodic Soils" (Drought Tips Number 92-33, University of California Cooperative Extension, 1993).

The following treatments were applied in three replications.

- i. Control.
- ii. Full rate of 99.5% pure gypsum to lower soil SAR-final levels to 3.
- iii. Full rate of VersaLime to lower the soil SAR-final levels to 3.
- iv. Full rate of 90% pure elemental sulfur (S°) to lower the soil SAR-final levels to 3.

Details of amendment rates for each treatment and replication are in Table 1 below.

Table 1. Details of Amendment Rates for each Treatment.

| Treatments and Replications | 99.5% Gypsum tons/plot | 90% Elemental Sulfur tons/plot | VersaLime tons/plot |
|-----------------------------|------------------------|--------------------------------|---------------------|
| R1T1 | 0 | 0 | 0 |
| R1T2 | 4.47 | 0 | 0 |
| R1T3 | 0 | 0 | 8.74 |
| R1T4 | 0 | 2.10 | 0 |
| R2T1 | 0 | 0 | 0 |
| R2T2 | 7.25 | 0 | 0 |
| R2T3 | 0 | 0 | 30.45 |
| R2T4 | 0 | 0.61 | 0 |
| R3T1 | 0 | 0 | 0 |
| R3T2 | 10.67 | 0 | 0 |
| R3T3 | 0 | 0 | 22.93 |
| R3T4 | 0 | 2.16 | 0 |
| Total | 22.40 | 4.87 | 62.14 |

Note: Gypsum and elemental sulfur were applied on June 29th, whereas, VersaLime was applied on July 23, 2015. After spreading, all of the amendments were rototilled into the soil. Control plots were also rototilled for uniformity purposes. Control structures for all of the treatments were fully opened right after the incorporation of the amendments in order to simulate free drainage and achieve maximum leaching conditions.

RESULTS AND DISCUSSION:

This is a preliminary report as the data is still being analyzed. The findings below are based on the statistical analysis of the 2016 and 2017 soil salt, Na⁺ and pH levels versus 2014 results by using SAS package 9.4 at 95% confidence interval. In addition, soil analysis results used for statistical analysis were averages of the zero to four feet depths of each plot (treatment).

At the Time of Tiling (2014):

At the time of tiling, all plots had moderately high salt levels with control plots having the lowest levels (EC mean = 7.39 dS/m) and gypsum plots having the highest levels (EC mean = 9.58 dS/m). The soil Na⁺ levels in all of the plots were high to very high with control having the lowest levels (SAR mean = 12.58) and gypsum plots having the highest levels (SAR mean = 18.36). Soil pH of all plots were close to neutral. Details are in Table 2.

Table 2. The Treatment means of the Soil Salt, Na⁺ and pH Levels at the Time of Tiling (2014).

| Soil Property | 2014 Treatment Means | | | |
|---------------|----------------------|--------|-----------|----------|
| | Control | Gypsum | VersaLime | E-Sulfur |
| EC (dS/m) | 7.39 | 9.58 | 9.19 | 8.91 |
| SAR | 12.58 | 18.36 | 16.33 | 16.58 |
| pH | 7.05 | 7.04 | 7.14 | 6.94 |

Two-years After Tiling and One-year After the Application of Soil Amendments (2016):

Statistically, there were no significant differences in the soil EC (salts), SAR (Na⁺) and pH levels (Table 3) compared to the levels at the time of tiling.

Table 3. 2016 Statistical Data of the Soil Salt, Na⁺ and pH Levels.

| Soil Properties | Mean | C.V. % | LSD | F-value | P > F |
|-----------------|-------|--------|------|---------|--------|
| EC (dS/m) | 3.75 | 18.70 | 1.32 | 3.82 | 0.0576 |
| SAR | 16.45 | 27.65 | 8.57 | 3.04 | 0.0924 |
| pH | 7.90 | 0.88 | 0.13 | 0.48 | 0.7074 |

Based on the differences in treatment means, compared to 2014, soil salt levels decreased in 2016 in all plots irrespective of the treatment effects under improved drainage due to tiling. The largest decrease was observed in control plots, followed by gypsum, VersaLime and E-sulfur. This is logical as initially gypsum, VersaLime and E-sulfur reactions lead to higher salt levels. In addition, despite having the highest EC levels at the time of tiling, gypsum plots recorded the highest decrease in EC after the control plots. Soil Na⁺ levels, however, increased in gypsum and E-sulfur plots by 17% and 10% respectively. In 2016, soil pH levels increased in all plots compared to 2014. The reason for higher soil pH levels in 2016 could be due to the higher soil moisture levels at the time of sampling in June 2016 when North Dakota Agriculture Weather Network (NDAWN) Langdon Station recorded a monthly total of 3.97" of rainfall. At the time of 2014 sampling in September, Langdon recorded a monthly total of 0.68" of rainfall. Detailed comparisons of treatment means are in Table 4.

Table 4. Comparison of 2016 and 2014 Treatment Means.

| Comparison of 2016 and 2014 Treatment Means | | | | |
|---------------------------------------------|------------|-----------|-------|------|
| Treatment | Year | EC (dS/m) | SAR | pH |
| Control | 2016 | 2.59 | 10.72 | 7.87 |
| | 2014 | 7.39 | 12.58 | 7.05 |
| | Difference | -4.80 | -1.86 | 0.81 |
| Gypsum | 2016 | 3.98 | 21.51 | 7.91 |
| | 2014 | 9.584 | 18.36 | 7.04 |
| | Difference | -5.59 | 3.15 | 0.86 |
| VersaLime | 2016 | 4.03 | 15.32 | 7.89 |
| | 2014 | 9.19 | 16.33 | 7.14 |
| | Difference | -5.16 | -1.01 | 0.75 |
| E-Sulfur | 2016 | 4.39 | 18.27 | 7.94 |
| | 2014 | 8.91 | 16.58 | 6.94 |
| | Difference | -4.51 | 1.68 | 0.99 |

Three-years After Tiling and Two-years After the Application of Soil Amendments (2017):

In 2017, soil SAR levels (Na^+) were significantly lower in control plots versus gypsum and VersaLime plots. This may be a result of control plots having the lowest EC and SAR levels at the time of tiling (2014). No significant differences were found in soil EC (salts) and pH. Details are in Table 5.

Table 5. 2017 Statistical Data of the Soil Salt, Na^+ and pH Levels.

| Soil Properties | Mean | C.V. % | LSD | F-value | P > F |
|------------------------|-------------|---------------|------------|----------------|-----------------|
| EC (dS/m) | 6.59 | 21.82 | 2.71 | 2.07 | 0.1829 |
| SAR | 15.15 | 15.14 | 4.32 | 5.88 | 0.0202 |
| pH | 7.92 | 1.62 | 0.24 | 0.49 | 0.6995 |

The comparisons of 2017 and 2014 treatment means showed a steady decrease in soil salt levels in 2017 as well. Like 2016, gypsum plots recorded highest decrease in EC after control plots. This could be due to the higher solubility and fast reacting nature of gypsum versus VersaLime and E-sulfur. Soil Na^+ levels decreased in control, gypsum and e-sulfur plots, whereas, an increase (SAR mean = 1.14) was observed in the VersaLime plots. Soil pH levels also increased in 2017 compared to 2014 in all plots. That may again be due to the higher soil moisture levels in June of 2017 when soil samples were taken as Langdon recorded 2.94" of rainfall during the month (Table 6).

Table 6. Comparison of 2017 and 2014 Treatment Means.

| Comparison of 2017 and 2014 Treatment Means | | | | |
|---------------------------------------------|------------|-----------|-------|------|
| Treatment | Year | EC (dS/m) | SAR | pH |
| Control | 2017 | 4.81 | 10.77 | 7.90 |
| | 2014 | 7.39 | 12.58 | 7.05 |
| | Difference | -2.58 | -1.81 | 0.84 |
| Gypsum | 2017 | 7.01 | 17.64 | 7.95 |
| | 2014 | 9.58 | 18.36 | 7.04 |
| | Difference | -2.56 | -0.72 | 0.90 |
| VersaLime | 2017 | 7.37 | 17.48 | 7.99 |
| | 2014 | 9.19 | 16.33 | 7.14 |
| | Difference | -1.82 | 1.14 | 0.85 |
| E-Sulfur | 2017 | 7.17 | 14.71 | 7.87 |
| | 2014 | 8.91 | 16.58 | 6.94 |
| | Difference | -1.73 | -1.86 | 0.93 |

Changes in Soil Salt and Sodium Levels in 2017 versus 2016:

Based on the differences in the treatment means, in 2017, soil salt levels increased in all plots versus 2016. This could be an effect of drier weather in 2017, which resulted in the accumulation of soluble salts in the first four feet depth instead of downward movement. In 2017, Langdon recorded 10.11" of rainfall with a Potential Evapotranspiration (PET) of 34.89" from May 1 to October 31. For the same period in 2016, Langdon recorded 23.11" of rainfall with a Potential Evapotranspiration of 31.47". Soil Na^+ levels increased in VersaLime plots in 2016, whereas, in 2017 increase was observed in VersaLime and control plots. Details are in Table 7.

Table 7. Comparison of 2017 and 2016 Treatment Means.

| Comparison of 2014 and 2017 Treatment Means | | | | |
|---------------------------------------------|------------|-----------|-------|-------|
| Treatment | Year | EC (dS/m) | SAR | pH |
| Control | 2017 | 4.81 | 10.77 | 7.90 |
| | 2016 | 2.59 | 10.72 | 7.87 |
| | Difference | 2.21 | 0.05 | 0.02 |
| Gypsum | 2017 | 7.01 | 17.64 | 7.95 |
| | 2016 | 3.98 | 21.51 | 7.91 |
| | Difference | 3.02 | -3.87 | 0.03 |
| VersaLime | 2017 | 7.37 | 17.48 | 7.99 |
| | 2016 | 4.03 | 15.32 | 7.89 |
| | Difference | 3.33 | 2.16 | 0.09 |
| E-Sulfur | 2017 | 7.17 | 14.71 | 7.87 |
| | 2016 | 4.39 | 18.27 | 7.94 |
| | Difference | 2.77 | -3.55 | -0.06 |

Relationship between Groundwater Levels and the Varying Salt and Sodium Levels

The fluctuations in seasonal rainfall and resulting groundwater levels did affect soil salt levels. Largest decrease in EC levels were recorded in 2016 with shallower groundwater levels and higher seasonal rainfall (23.11"). In 2017, soil EC levels went up versus 2016, under lower groundwater levels and lower seasonal rainfall (10.11"). Overall, average individual groundwater levels in 2017 were 1.07 to 1.98 feet lower than 2016 (Table 8) with a rainfall shortfall of 13.0". No effect of groundwater levels were recorded on SAR levels in 2015, 2016 and 2017 as gypsum plots had the highest means and control had the lowest means in all three years. The changes in soil pH were found to be consistent with soil moisture availability. Considering the four feet sampling depth, higher rainfall combined with shallower groundwater levels will result in higher soil moisture levels and high soil pH.

Table 8. Comparison of 2016 and 2017 Groundwater Level Treatment Means

| Treatment | 2015 Means | 2016 Means | 2017 Means |
|-----------|------------|------------|------------|
| Control | 4.44 | 3.78 | 4.98 |
| Gypsum | 4.53 | 3.49 | 5.20 |
| VersaLime | 4.96 | 4.09 | 5.75 |
| E-Sulfur | 3.99 | 3.55 | 5.11 |

Water Quality Draining from the Research Project Site for Human and Livestock Health

All minerals and nutrients affecting human and livestock health, were found to be within the acceptable limits in the samples coming out the Langdon REC Groundwater Management Research Project site.

CONCLUSION:

Based on four year's data, soil salt levels consistently decreased in 2016 and 2017 compared to the levels at the time of tiling. However, sodium levels did increase in 45.83% of the individual soil samples in 2016 as well as in 2017. Increased sodium levels mean higher amendment costs and longer wait to achieve maximum productivity. Landowners considering tiling, should consider the following recommendations before installing an expensive tile system. That will save them money and ensure correct use of technology:

- Potential fields “should be analyzed for salts and sodium”.
- If sodicity is established, “application of soil amendments should be considered before tiling”.

Langdon REC Foundation Seed Stocks Program

The Langdon REC supports a Foundation Seed Stocks Program to help increase and distribute the newest NDSU varieties of HRSW, Durum, Barley, Soybeans and Flax. We also periodically increase seed for the University of Minnesota and South Dakota Ag Experiment Station. Each year approximately 350 acres are planted for the FSS program. The harvested acreage is available for sale to producers and seedsmen in the region. The varieties of crops that are available for the 2018 growing season are listed below:

HRSW – Glenn, Faller, Prosper, Elgin-ND, Linkert, Bolles, ND VitPro

Barley – Lacey

Flax – Omega

Soybeans - ND Henson, ND17009GT

Growers who have grown seed for certification in one of the last four years who request seed prior to December 1 will be guaranteed an allocation. Any seed inventories available after December 1 will be sold on a first come, first serve basis. Seed availability and prices may be obtained by calling the Langdon Research Extension Center at 701-256-2582.
