

North Dakota Sunflower

Variety Trial Results for 2024 and Selection Guide

Ana Carcedo (North Dakota State University, Main Station); B. Hulke, B. Koehler, Z. Tippins, and A. Berger (Sunflower Unit, U.S. Department of Agriculture-Agricultural Research Service, Fargo); Mike Ostlie, Kristin Simons (Carrington Research Extension Center); Leandro Bortolon, Austin Kraklau, Jayden Hansen (North Central Research Extension Center); Bryan Hanson, Lawrence Henry, Richard Duerr (Langdon Research Extension Center); John Rickertsen (Hettinger Research Extension Center), Justin Jacobs (Williston REC).

Sunflower production in North Dakota has undergone significant changes in recent years, particularly in the distribution between oil-type and non-oil-type sunflowers. The state's sunflower acreage reached a peak of 733,000 acres in 2020 but has since declined to 305,000 acres in 2024. In 2023, oil-type sunflowers covered 500,000 acres, yielding over 965 million pounds. In contrast, non-oil-type sunflowers, though still important, occupied only 75,000 acres and produced 155 million pounds. While oil-type sunflower production has fluctuated in recent years, it remains the dominant crop in the state, whereas non-oil sunflower acreage and production have remained relatively stable.

Figure 1. Sunflower Production, and Acres Planted North Dakota 2000-2024. Data from USDA-NASS.
Total production and acres are divided in Oil (dark grey) and Non-Oil types (light grey).

- Table 8. Sunflower Confection (Non-oil). Data from Langdon Research Extension Center.
- Table 9. Sunflower Oilseed. Data from Langdon Research Extension Center.
- Table 10. Sunflower Oilseed. Data from Hettinger Research Extension Center.

Data from Carrington REC was not included due to hail damage.

About This Publication

Variety trial data from all North Dakota State University Research Extension Centers for all crops can be found at www.ag.ndsu.edu/varietytrials and the variety selection tool at <https://vt.ag.ndsu.edu/>.

The agronomic data presented in this publication are from replicated research plots using experimental designs that enable the use of statistical analysis. The least significant difference numbers beneath the columns in tables are derived from the statistical analyses. If the difference between two varieties exceeds the LSD value, it means that with 95% or 90% probability (LSD 5% or 10% level), the higher-yielding variety has a significant yield advantage. If the difference between two varieties is less than the LSD value, then the variety yields are considered similar.

The coefficient of variation (CV) is a measure of variability in the trial and is expressed as a percentage. Large CVs mean a large amount of variation that could not be attributed to differences in the varieties. Only compare values within the table and look for trends for the desired trait among different experimental sites and years.

Sunflower harvest yields were adjusted to 10% moisture. Most of the tables have footnotes explaining information in the table under which they appear. Traits to consider when selecting a sunflower hybrid include yield potential in your area, oil content (for the oil types), test weight, reaction to problematic diseases and insects, maturity date and the weed control system. When selecting a confection sunflower hybrid, the seed size is very important.

Among similar-yielding oilseed hybrids, select the one with the highest oil content. Oil content is intended to differentiate between hybrids at one location. LSD values should be used to determine differences between hybrids. The oilseed crushing market pays a premium for more than 40% oil (at 10% moisture) and discounts for less than 40% oil. Another factor to consider is the oil type. Hybrids are available with traditional (linoleic), midoleic (NuSun) and high-oleic oil compositions. Markets may pay a premium based on the composition of the oil produced by a particular hybrid.

Maturity is especially important if planting is delayed. Yield and oil content often are reduced when a hybrid is damaged by frost before it is fully mature. Often with delayed planting, only an early hybrid will mature and exhibit its full yield potential. An early hybrid likely will be drier at harvest than a later-maturing hybrid, thus reducing drying costs.

The most economical and effective means of managing sunflower diseases and other pests is to plant resistant or tolerant hybrids and keep a minimum of four years of rotation between successive sunflower crops. Most commercial sunflower hybrids in the U.S. have resistance to downy mildew and rust. Some hybrids also may exhibit tolerance to Phomopsis stem canker or sunflower midge. Clearfield® and ExpressSun™ hybrids are resistant to Beyond Xtra® and Express® herbicides, respectively. Consult the seed company for information on the reaction of a particular hybrid to diseases and other pests that may pose risks in your growing area.

When selecting a high-yielding and good-quality hybrid, use data that summarize several years and locations. Choose the hybrid that, on average, performs the best at multiple locations near you during several years.

Research specialists and technicians contributed to the fieldwork and data compilation. Secretaries contributed in entering data into the respective sections of this document. We greatly appreciate the assistance provided by everyone involved.

Presentation of data for the varieties tested does not imply approval or endorsement by the authors or agencies conducting the tests. NDSU approves the reproduction of any table in this publication only if no portion is deleted, appropriate footnotes are given, the order of the data is not rearranged and NDSU is credited for the data.
